(57) **ABSTRACT**

The ceiling mounted ventilation fan with illumination employs a configuration in which a second opening for guiding light from an illumination unit into the room is formed in a lower part of a main housing and in which a air inlet on a fan casing of a fan unit is provided so as to open toward upper part of the main housing. Thus the air inlet of the fan unit opens in a direction opposite to the second opening communicating with inside of the room. As a result, sounds such as operation noises from the fan unit that are transmitted to outside of the fan unit chiefly through the air inlet can be made to resist being transmitted through the second opening into the room, so that the noises can be reduced.

CEILING MOUNTED VENTILATION FAN WITH ILLUMINATION

TECHNICAL FIELD

The present invention relates to a ventilation fan for push-pull ventilation system (i.e., a ventilation fan for air supply and exhaust systems) and, more particularly, to a noise reduction structure of a ceiling mounted ventilation fan with illumination for push-pull ventilation system.

BACKGROUND ART

As such a type of ceiling mounted ventilation structure with illumination, there has conventionally been known a structure with use of downlight, for instance. FIG. 8 shows an example of a conventional ceiling mounted ventilation structure with illumination (see Patent Document 1, for instance).

As shown in FIG. 8, the conventional ceiling mounted ventilation structure **108** with illumination has a recessed portion (dent portion) **102** provided on a ceiling **101**, an electric bulb **105** that is enclosed by a moisture-proof cover **104** and that is placed in the recessed portion **102** with a rubber packing **103** therebetween, a ventilation opening **106** formed on a part of a peripheral wall of the recessed portion **102**, and a duct **107** connected to the ventilation opening **106**.

The ceiling mounted ventilation structure **108** with illumination is capable of attaining the function of room ventilation while attaining the function as downlight.

PATENT DOCUMENT

Patent Document 1: JP S57-68426 U

SUMMARY OF INVENTION

Technical Problem

In the conventional ceiling mounted ventilation structure **108** with illumination is employed a structure in which the recessed portion **102** is formed in shape of a circular truncated conical cylinder and in which an inner wall surface of the recessed portion **102** is used as a reflecting surface so as to reflect light from the electric bulb **105** toward underside, that is, toward inside of a room. The employment of such a structure enhances the function of downlight in the ceiling mounted ventilation structure **108** with illumination.

The formation of the recessed portion **102** in the shape of the circular truncated conical cylinder, however, causes a problem in that the shape functions as so-called megaphone by which air blow noises made in the ceiling mounted ventilation structure **108** with illumination and operation noises from a fan or the like may be transmitted to the inside of the room or to farther sites with enhancement of directivity of such noises.

Accordingly, an object of the present invention, lying in solving the above-described issues, is to provide a ceiling mounted ventilation fan with illumination capable of suppressing noise conducted to room inside.

Solution to Problem

In order to achieve the object, the invention is configured as follows.

2

According to a first aspect of the invention, there is provided a ceiling mounted ventilation fan with illumination comprising a main housing, and a fan unit and lighting equipment installed in the main housing,

the main housing comprising:

a first opening connected to an air outlet of the fan unit, the first opening communicating with a duct, and

a second opening formed in a lower part of the main housing so as to communicate with inside of a room, the lighting equipment comprising:

an illumination unit, and

a lighting cover placed in the main housing so as to surround the illumination unit, the lighting cover having a reflecting surface which reflects light from the illumination unit so as to guide the light through the second opening into the room,

the fan unit comprising:

a fan, and

a fan casing placed so as to surround the fan, the fan casing having an air inlet opening toward upper part of the main housing, wherein

air introduced through the second opening into the main housing is sucked through the air inlet of the fan casing into the fan unit and is discharged by the fan unit through the first opening into the duct.

According to a second aspect of the invention, there is provided a ceiling mounted ventilation fan with illumination according to the first aspect, wherein

an electrical unit for the fan unit or the lighting equipment is placed on an area facing the second opening, on an inner wall surface of the upper part of the main housing, and

the fan unit is placed in the main housing so that a distance **L1** from the inner wall surface of the upper part of the main housing to the air inlet of the fan casing is greater than a height **L2** of the electrical unit.

According to a third aspect of the invention, there is provided a ceiling mounted ventilation fan with illumination according to the second aspect, further comprising leg parts that support the fan casing on an inner wall surface of the lower part of the main housing, wherein

the fan unit is movable between a placement position for the fan unit in the main housing and a maintenance position for the fan unit over the second opening by slide movement of the leg parts along the inner wall surface of the lower part of the main housing.

According to a fourth aspect of the invention, there is provided a ceiling mounted ventilation fan with illumination according to the third aspect, further comprising guiding members that are engaged with the leg parts so as to guide the slide movement of the leg parts.

Effects of Invention

According to the invention, the ceiling mounted ventilation fan with illumination employs the configuration in which the second opening for guiding the light from the illumination unit into the room is formed in the lower part of the main housing and in which the air inlet on the fan casing of the fan unit is provided so as to open toward the upper part of the main housing. Thus the air inlet of the fan unit opens in the direction opposite to the second opening communicating with the inside of the room. Accordingly, sounds such as operation noises from the fan unit that are transmitted to the outside of the fan unit chiefly through the air inlet can be made to resist being transmitted through the second opening into the room. As a result, the ceiling

3

mounted ventilation fan with illumination can be provided by which the noise conducted to room inside is suppressed.

BRIEF DESCRIPTION OF DRAWINGS

FIG. 1 is a perspective view of a ceiling mounted ventilation fan with illumination in accordance with an embodiment 1 of the invention;

FIG. 2 is a sectional view of the ceiling mounted ventilation fan with illumination of the embodiment 1 as seen looking from a Y direction;

FIG. 3 is a sectional view of the ceiling mounted ventilation fan with illumination of the embodiment 1 as seen looking from an X direction;

FIG. 4 is an exploded view of a fan unit of the ceiling mounted ventilation fan with illumination of the embodiment 1;

FIG. 5 is a sectional view of the ceiling mounted ventilation fan with illumination of the embodiment 1 as seen looking from the Y direction with the fan unit moved to a maintenance position;

FIG. 6 is a sectional view of a ceiling mounted ventilation fan with illumination in accordance with an embodiment 2 of the invention;

FIG. 7 is a sectional view of a ceiling mounted ventilation fan with illumination in accordance with an embodiment 3 of the invention; and

FIG. 8 is a sectional view showing a conventional ceiling mounted ventilation structure with illumination.

DESCRIPTION OF EMBODIMENTS

Before the description of the present invention proceeds, it is to be noted that like parts are designated by like reference numerals throughout the accompanying drawings. Hereinbelow, embodiments of the present invention will be described in detail with reference to the accompanying drawings.

Embodiment 1

FIG. 1 shows a perspective view of a ceiling mounted ventilation fan 1 with illumination in accordance with an embodiment 1 of the invention. FIG. 2 shows a sectional view (partly sectional view) thereof as seen looking from a Y direction in FIG. 1. FIG. 3 shows a sectional view (partly sectional view) thereof as seen looking from an X direction in FIG. 1. In FIG. 1, the X direction and the Y direction are horizontal directions that are orthogonal to each other and a Z direction is a vertical direction that is orthogonal to the X direction and to the Y direction.

As shown in FIGS. 1, 2 and 3, the ceiling mounted ventilation fan 1 with illumination includes a main housing 10 that is generally shaped like a box, and a fan unit 20 and lighting equipment 30 that are placed in the main housing 10.

The main housing 10 has a first opening 11 connected to an air outlet of the fan unit 20 and a second opening 12 communicating with inside of a room through a ceiling opening 3 formed on a ceiling 2. The first opening 11 formed on a side part of the main housing 10 is connected to a duct connection part 13 so as to communicate with a duct 14 through the duct connection part 13. Though FIGS. 1 and 2 show an example in which the first opening 11 is formed on the side part of the main housing 10 and in which the second

4

opening 12 is formed in a lower part of the main housing 10, the first opening 11 may be formed on upper part of the main housing 10.

The fan unit 20 has a fan 21, a motor 22 for rotating the fan 21, and a fan casing 23 that is placed so as to surround the fan 21. The fan unit 20 is fixed to an inner wall of the upper part of the main housing 10. On the fan casing 23 of the fan unit 20 is formed an air inlet 24 that opens toward an inner wall surface of the upper part of the main housing 10 (that is, the air inlet 24 is provided so as to open upward in the drawing). Air in the main housing 10 is taken into the fan casing 23 through the air inlet 24 opening upward and is thereafter discharged through the air outlet of the fan casing 23, the first opening 11 and the duct connection part 13 into the duct 14. Though a centrifugal fan unit such as a multi-blade fan will be described below as an example of type of the fan unit 20, there may be employed other types of fan units that are capable of attaining such a function of discharge. A detailed structure of the fan unit 20 will be described later.

The lighting equipment 30 includes a lamp (illumination unit) 31, a lighting cover 32 that surrounds the lamp 31, and a lamp mounting fixture 33 for detachably fixing the lamp 31 and the lighting cover 32 onto the inner wall of the main housing 10. The lamp 31 and the lighting cover 32 are placed on a central axis P so that center positions thereof substantially coincide with a center of the second opening 12 of the main housing 10 as seen looking in a vertical direction. In addition to a function of detachably fixing the lamp 31, the lamp mounting fixture 33 has a function of supplying the lamp 31 with electricity. As the lamp 31, a fluorescent lamp or an LED may be used in place of the so-called electric bulb. A relation of placement between the lamp 31, the lighting cover 32 and the second opening 12 of the main housing 10 is not limited to such a relation that the center positions of those substantially coincide with one another as seen looking in the vertical direction. The relation of placement has only to be such that light from the lamp 31 is cast into the room through the second opening 12.

The lighting cover 32 is generally formed in shape of a circular truncated conical cylinder so that a diameter of a lower end 32b of the cover 32 is greater than that of an upper end 32a thereof. The lighting cover 32 is formed so as to have a length (size in the vertical direction) that covers an overall surrounding side part of a light emitting part of the lamp 31 provided inside the cover 32. Between the lighting cover 32 and the lamp 31 is secured such a gap as prevents contact therebetween.

An inner circumferential surface of the lighting cover 32 forms a reflecting surface 32c that reflects the light from the lamp 31 toward the second opening 12 (i.e., downward). The lighting cover 32 having such a reflecting surface 32c makes it possible for the light from the lamp 31 to make into direct light and reflected light and to efficiently irradiate the inside of the room.

The lighting equipment 30 includes a lid (lid member) 34 for sealing an opening of the lower end 32b of the lighting cover 32. The lid 34 is detachably attached to the lower end 32b of the lighting cover 32 so as not to be in contact with the lamp 31. The lid 34 is detached from the lighting cover 32 on occasion of replacement of the lamp 31 and the like.

Onto the inner wall surface of the upper part of the main housing 10 above the lamp mounting fixture 33 of the lighting equipment 30, an electrical unit 40 is fixed that contains various electrical components for energizing the fan unit 20 and the lighting equipment 30 or controlling operations thereof. The motor 22 of the fan unit 20 and the

5

lamp mounting fixture **33** of the lighting equipment **30** are electrically connected to the electrical unit **40**. The lamp mounting fixture **33** is detachably fixed through the electrical unit **40** onto the inner wall surface of the upper part of the main housing **10**.

A flange **35** (opening member) that is an annular member is mounted on the ceiling opening **3**. The flange **35** serves as a dressing member that covers a lower periphery and an inner circumferential surface of the ceiling opening **3** so as to prevent the ceiling opening **3** from being directly seen from the inside of the room. The flange **35** is attached with the lower periphery of the ceiling opening **3** biased upward through biasing members (such as wire-like springs) **36** that each have one end engaged with the main housing **10** and the other end engaged with the flange **35**. When the flange **35** is released from the ceiling opening **3**, the biasing members **36** prevent the flange **35** from falling down. FIG. 1 shows a state in which the flange **35** has been released from the ceiling opening **3**.

As shown in FIG. 2, an annular gap **S** for air intake is provided between the lower end **32b** of the lighting cover **32** and an edge part of the second opening **12** of the main housing **10**, more particularly, an inside edge part of the flange **35**. An introduction path for indoor air is formed so that the indoor air introduced through the ceiling opening **3** on which the flange **35** is placed is then introduced through the annular gap **S** for air intake and the second opening **12** into the main housing **10**.

On the lower end **32b** of the lighting cover **32** is formed an annular brim **37** that is formed so as to protrude toward surroundings thereof.

Once the lamp **31** is turned on in the ceiling mounted ventilation fan **1** with illumination that has such a configuration, the light from the lamp **31** is introduced through the lid **34** and the ceiling opening **3** (opening of the flange **35**) into the room and light from a circumferential surface of the side part of the lamp **31** is reflected downward by the reflecting surface **32c** of the lighting cover **32** and is subsequently introduced through the lid **34** and the ceiling opening **3** into the room. Thus the ceiling mounted ventilation fan **1** with illumination functions as a downlight.

When the fan **21** is rotated by the motor **22** of the fan unit **20**, the indoor air is introduced through the ceiling opening **3** and the annular gap **S** for air intake into the main housing **10**. In the annular gap **S** for air intake, wind noises produced by the lower end **32b** of the lighting cover **32** and the like are reduced by the annular brim **37** formed on the lower end **32b** of the lighting cover **32**. The air introduced into the main housing **10** is taken into the fan casing **23** through the air inlet **24** opening upward and is discharged from the fan unit **20** through the first opening **11** and the duct connection part **13** into the duct **14**. Thus the ceiling mounted ventilation fan **1** with illumination functions as a ventilation fan.

With reference to FIG. 4 that is an exploded view of the fan unit **20**, hereinbelow, the detailed structure of the fan unit **20** will be described later.

As shown in FIG. 4, the fan unit **20** includes the fan **21**, the motor **22** for rotating the fan **21**, and the fan casing **23** that is placed so as to surround the fan **21**. The fan casing **23** has a so-called voluted shape. An opening is formed on a center of each of top and bottom surfaces thereof and the air outlet **25** is formed on a side surface thereof that is a terminal part of the voluted shape. The opening at the center of the bottom surface of the fan casing **23** is sealed by attachment of the motor **22** through a sealing member **26** in shape of a disc. The opening at the center of the top surface of the fan casing **23** forms the air inlet **24**.

6

On an edge of the top surface of the fan casing **23** are formed two mounting parts **27** protruding outward along the upper surface. As shown in FIGS. 2 and 3, the mounting parts **27** are screwed onto mounting members **15** fixed to the inner wall surface of the upper part of the main housing **10**, and the fan unit **20** is thereby detachably fixed to the main housing **10**.

As shown in FIG. 4, three leg parts **28** extending downward are provided on the side surface of the fan casing **23**. As shown in FIGS. 2 and 3, the leg parts **28** each have a lower end **28a** shaped like a letter L. Each lower end **28a** is placed on an inner wall surface of the lower part of the main housing **10** and thus supports the fan unit **20** on the inner wall surface of the lower part. In the embodiment 1, the lower ends **28a** of the leg parts **28** are not fixed to the lower part of the main housing **10** but only support the fan unit **20**. Consequently, the fan unit **20** can be slid in the X direction in a state in which the fixation between the mounting parts **27** and the mounting members **15** has been released, as will be described later.

As shown in FIG. 3, the lower ends **28a** of the leg parts **28**, on left and right sides in the drawing, of the fan unit **20** are each shaped like a letter L so as to extend outward in the Y direction, and extremity sides **28c** of the lower ends **28a** are formed so as to extend in parallel with the X direction. Guiding parts **16** that are to be engaged with the lower ends **28a** of the leg parts **28** on the left and right sides in the drawing are formed on inner wall surfaces of side parts of the main housing **10** that face each other. The guiding parts **16** are formed so as to extend in the X direction in the drawing. With the guiding parts **16** engaged with the lower ends **28a** of the leg parts **28** on the left and right sides in the drawing, the extremity sides **28c** of the lower ends **28a** are guided, so that slide movement of the leg parts **28** in the X direction is thereby guided. The guiding parts **16**, however, may be omitted.

As shown in FIG. 2, a guiding bar **17** extending in the X direction is provided on the inner wall surface of the lower part of the main housing **10**. One end of the guiding bar **17** is fixed to the inner wall surface of the side part of the main housing **10** and the other end thereof is fixed to a stopper **18** fixed onto the inner wall surface of the lower part. A hole **28b** is formed on the leg part **28** at center of the fan unit **20** (see FIG. 4). The guiding bar **17** is inserted into the hole **28b**. Thus the slide movement of the leg part **28** at the center in the X direction is guided by the guiding bar **17** and a range of the slide movement of the leg part **28** in the X direction is restricted to between both the ends of the guiding bar **17**.

FIG. 2 shows a state in which the fan unit **20** is placed in a placement position **R1** where the fan unit **20** is connected through the first opening **11** to the duct connection part **13**, in which the fan unit **20** is supported by the leg parts **28**, and in which the mounting parts **27** and the mounting members **15** are fixed to each other. A relation of placement between the fan unit **20** and the electrical unit **40** in a direction of height is set so that a distance **L1** from the inner wall surface of the upper part of the main housing **10** to the air inlet **24** of the fan casing **23** is greater than a height **L2** of the electrical unit **40** fixed onto the inner wall surface of the upper part of the main housing **10** in such a state.

Hereinbelow will be described procedures of maintenance for the motor **22** of the fan unit **20** in the ceiling mounted ventilation fan **1** with illumination having such a configuration.

As shown in FIG. 1, initially, the flange **35** is detached along with the biasing members **36** from the main housing **10**. Subsequently, the lighting equipment **30** is detached

from the main housing 10 by release of the lamp mounting fixture 33 from the main housing 10 and is then taken out through the second opening 12 into the room.

After that, the screw fixation between the mounting parts 27 of the fan casing 23 and the mounting members 15 is released. With the release from the fixation between the mounting parts 27 and the mounting members 15, the fan unit 20 is supported only by the three leg parts 28 from the underside.

Subsequently, the fan unit 20 placed in the placement position R1 is slid in the X direction so as to be placed in a maintenance position R2 that is over the second opening 12 (see FIG. 5). In the slide movement of the fan unit 20, as shown in FIG. 3, the lower ends 28a of the leg parts 28 on the left and right sides in the drawing are guided by the guiding parts 16 and the leg part 28 at the center is guided by the guiding bar 17. Therefore, the slide movement of the fan unit 20 can smoothly be performed. As shown in FIG. 5, the range of the slide movement of the fan unit 20 is restricted by contact of the lower end 28a of the leg part 28 at the center with the stopper 18, and the fan unit 20 is placed in the maintenance position R2 in a state with the contact. Thus positioning in the maintenance position R2 can easily be performed and excessive slide movement beyond the maintenance position R2 can be prevented. Interference between the fan unit 20 and the electrical unit 40 is prevented when the fan unit 20 is moved to the maintenance position R2, because the height L2 of the electrical unit 40 fixed onto the inner wall surface over the second opening 12 in the main housing 10 is set so as to be smaller than the distance L1 from the inner wall surface of the upper part of the main housing 10 to the air inlet 24 of the fan unit 20.

After that, maintenance operations, such as detachment of the motor 22, for the fan unit 20 placed in the maintenance position R2 are performed through the second opening 12. Once the maintenance operations are completed, the fan unit 20 is slid from the maintenance position R2 to the placement position R1. For the slide movement also, the guidance for the slide movement of every leg part 28 smoothes the movement and facilitates the positioning of the fan unit 20 in the placement position R1. After that, the screw fixation of the fan unit 20, attachment operations for the lighting equipment 30, and the like are performed.

In the embodiment 1, the ceiling mounted ventilation fan 1 with illumination employs the configuration in which the second opening 12 for guiding the light from the lamp 31 into the room is formed in the lower part of the main housing 10, and the fan casing 23 of the fan unit 20 employs the configuration in which the air inlet 24 is provided so as to open toward the upper part of the main housing 10. The bottom surface side of the fan casing 23 of the fan unit 20 is sealed by the attachment of the motor 22 through the sealing member 26 to the bottom surface side of the fan casing 23. Thus the air inlet 24 of the fan unit 20 opens in a direction opposite to the second opening 12 communicating with the inside of the room. As a result, sounds such as operation noises from the fan unit 20 (air blow noises, operation noises from the motor 22, and the like) that are transmitted to the outside of the fan unit 20 chiefly through the air inlet 24 can be made to resist being transmitted toward the second opening 12 in the main housing 10. Consequently, the ceiling mounted ventilation fan with illumination can be provided by which sounds such as operation noises from the fan unit 20 can be made to resist being transmitted through the second opening 12 into the room so that the noises that are transmitted into the room can be reduced.

Maintenance property for the fan unit 20 can be improved by the employment of the configuration in which the fan unit 20 can be slid between the placement position R1 and the maintenance position R2 in the main housing 10. By the provision of the members for guiding the slide movement of the fan unit 20, the slide movement can be smoothed and property of the positioning of the fan unit 20 in the placement position R1 and the maintenance position R2 can be improved.

The noises can further be reduced by such a contrivance for a structure of the lighting equipment 30 as in the embodiment 1 in addition to the noise reduction effect attained by such placement and configuration of the air inlet 24 of the fan unit 20.

In the embodiment 1, specifically, the lighting cover 32 that is placed so as to surround the lamp 31 has the cylindrical lower end 32b sealed with the lid 34. Thus passage of air through between the lamp 31 and the lighting cover 32 is restricted. This reduces propagation into the room of air blow noises caused by operation of the fan unit 20 placed in the main housing 10, operation noises from the motor 22 and the like with enhancement of directivity thereof that is caused by the lighting cover 32 that is generally in shape of the circular truncated conical cylinder and that functions as a megaphone. In particular, the lighting cover 32 is often generally shaped like the circular truncated conical cylinder because the cover 32 is required to have the reflecting surface 32c for the light from the lamp 31. There is a high possibility that the lighting cover 32 with such a shape functions as a so-called megaphone. The provision in the lighting cover 32 of the lid 34 that restricts the passage of air effectively reduces the propagation into the room of the sounds produced in the main housing 10 with enhancement of directivity thereof.

Though an example provided with the lid 34 for sealing the lower end 32b of the lighting cover 32 has been described above, the invention is not limited only to such a configuration. Provision of members (restriction members) capable of restricting the passage of air through between the lighting cover 32 and the lamp 31 ensures the same effect as that of the provision of the lid 34. For instance, restriction members that seal the upper end 32a may be provided in the lighting cover 32 with the lower end 32b opened. Alternatively, restriction members that seal the lower end 32b of the lighting cover 32 may be provided, with the upper end 32a opened. There may be provided both the restriction members that seal the upper end 32a of the lighting cover 32 and the restriction members that seal the lower end 32b thereof.

Such restriction members have only to have a configuration in which a function of restricting the passage of air through between the lighting cover 32 and the lamp 31 is attained. The configuration is not limited only to a configuration that completely shuts off the passage of air, and the passage of air has only to be restricted in general. For instance, the passage of air has only to be restricted in general even if openings required for the attachment of the lamp 31, power supply and/or the like are provided in the restriction members.

The lighting cover 32 may be generally shaped like a polygonal truncated prismoidal cylinder, a hemisphere or the like, other than the circular truncated conical cylinder. The restriction members may integrally be formed with the lighting cover 32.

The annular gap S for air intake has only to be formed around the lower end 32b of the lighting cover 32 and has only to be formed between the lower end 32b of the lighting

cover **32** and the flange **35**, between the lower end **32b** and the second opening **12**, or between the lower end **32b** and the ceiling opening **3**.

Sizes (area) of the annular gap **S** for air intake have only to be determined in design in consideration of specifications (air flow, static pressure and the like) of the fan unit **20**, sizes of the lamp **31** and the lighting cover **32**, a size of the ceiling opening **3**, and the like.

Embodiment 2

The invention is not limited to the embodiment described above and can be embodied in other various manners. For instance, FIG. **6** shows a configuration of a ceiling mounted ventilation fan **51** with illumination in accordance with an embodiment 2 of the invention. The same component members as those of the ceiling mounted ventilation fan **1** with illumination of the embodiment 1 are designated by the same reference numerals, and description thereof is omitted.

The ceiling mounted ventilation fan **51** with illumination of the embodiment 2 shown in FIG. **6** is different from the embodiment 1 described above in that an electrical unit **52** is mounted on the inner wall surface of the upper part of the main housing **10** so as to avoid interference with a lamp mounting fixture **53** in the main housing **10**. A relation between a height **L2** of the electrical unit **52** and the distance **L1** from the inner wall surface of the upper part of the main housing **10** to the air inlet **24** of the fan unit **20** is set so as to be $L2 < L1$ as in the embodiment 1. A height **L3** of the lamp mounting fixture **53** is set so that a relation $L3 < L1$ holds.

In the embodiment 2, the noise reduction effect for the fan unit **20** can be obtained as in the embodiment 1 and the maintenance property for the fan unit **20** can be improved because interference between the fan unit **20** and the electrical unit **52** can be prevented in the maintenance position. There is another advantage therein in that the lighting equipment having a comparatively great height can be provided therein because the electrical unit **52** is placed so as to avoid the interference with the lamp mounting fixture **53**.

Embodiment 3

FIG. **7** shows a configuration of a ceiling mounted ventilation fan **61** with illumination in accordance with an embodiment 3 of the invention. In the ceiling mounted ventilation fan **61** with illumination of the embodiment 3 shown in FIG. **7**, a configuration is employed in which a mounting member **62** for fixing the fan unit **20** onto the inner wall surface of the upper part of the main housing **10** and a mounting part **63** of the fan casing **23** are fixed in an inclined state by a screw. As shown in FIG. **7**, specifically, the mounting part **63** and the mounting member **62** are inclined so that an axial direction of the screw that fixes the mounting part **63** to the mounting member **62** is generally oriented toward a center of the second opening **12**.

Such a configuration improves visibility and working property (working property in the screw fixation with use of a screwdriver or the like) through the second opening **12** for the screw that fixes the mounting part **63** to the mounting member **62** and thus improves working property in maintenance for the fan unit **20**.

Though examples with use of the lighting equipment **30** having a configuration in which the lower end **32b** of the lighting cover **32** is sealed with the lid **34** have been described for the above embodiments 1 through 3, the form of the lighting equipment is not limited in the invention.

Even if lighting equipment having a configuration in which upper and lower ends of the lighting cover are opened is used, noises that are transmitted into the room can be reduced by the upward placement of the air inlet **24** of the fan unit **20**.

Working Example 1

For the ceiling mounted ventilation fan **1** with illumination of the embodiment 1, noises during the operation were measured in the configuration (working example) in which the air inlet **24** of the fan unit **20** was opened toward the inner wall surface of the upper part of the main housing **10** (i.e., opened upward) and the configuration (comparative example) in which the air inlet of the fan unit was opened toward the inner wall surface of the lower part of the main housing (i.e., opened downward). As the fan unit, a fan unit of multiblade fan type with an air flow of 92 CFM was used.

In a test chamber in which sounds from outside were shut off, the noises were measured at three sites in total, i.e., at two sites 1 m apart leftward and rightward from the ceiling mounted ventilation fan with illumination in the horizontal direction and one site 1 m apart downward therefrom.

Results in the ceiling mounted ventilation fan with illumination of the comparative example were 38.9 dB at the left measurement point, 39.4 dB at the right measurement point, and 43.9 dB at the lower measurement point. By contrast, results in the ceiling mounted ventilation fan with illumination of the working example were 36.2 dB at the left measurement point, 36.4 dB at the right measurement point, and 42.9 dB at the lower measurement point.

The results of the measurement indicate that the noises of the ceiling mounted ventilation fan with illumination of the working example were reduced at all the measurement points in comparison with the comparative example and that the noise reduction effect by the working example was greater.

It is to be noted that, by properly combining the arbitrary embodiments of the aforementioned various embodiments, the effects possessed by them can be produced.

Although the present invention has been fully described in connection with the preferred embodiments thereof with reference to the accompanying drawings, it is to be noted that various changes and modifications are apparent to those skilled in the art. Such changes and modifications are to be understood as included within the scope of the present invention as defined by the appended claims unless they depart therefrom.

The invention claimed is:

1. A ceiling mounted ventilation fan with illumination comprising: a main housing, a fan unit and lighting equipment installed in the main housing, the main housing comprising:
 a first opening connected to an air outlet of the fan unit, the first opening communicating with a duct, and
 a second opening provided in a lower part of the main housing so as to communicate with an interior of a room,
 the lighting equipment comprising:
 an illumination unit, and
 a lighting cover attached to the main housing and provided in the main housing so as to surround the illumination unit, the lighting cover having a reflecting surface which reflects light from the illumination unit so as to guide the light through the second opening into the room,
 the fan unit comprising:
 a fan, and
 a fan casing positioned at a first position, spaced, in a horizontal direction, from a second position that is above the second opening, the fan casing surrounding the fan, the fan casing having an air inlet opening directed upwardly, wherein
 air is introduced through the second opening into the main housing, and the introduced air is sucked through the air inlet of the fan casing into the fan unit and is discharged through the first opening into the duct by the fan unit, and
 the ceiling mounted ventilation fan further comprising:
 a first mounting member fixed on an upper wall of the main housing, and
 a second mounting member fixed on the fan casing, wherein
 the first mounting member and the second mounting member are inclined so that respective inclined surfaces of the first mounting member and the second mounting member face toward the second opening, and the fan is fixed to the upper wall of the main housing by fixing the inclined surface of the first mounting member to the inclined surface of the second mounting member.
 2. The ceiling mounted ventilation fan with illumination according to claim 1, wherein
 an electrical unit for the fan unit or the lighting equipment is placed on an area facing the second opening, on an inner surface of the upper wall of the main housing, and
 the fan unit is provided in the main housing so that a distance L1 from the inner surface of the upper wall

12

of the main housing to the air inlet of the fan casing is greater than a height L2 of the electrical unit.

3. The ceiling mounted ventilation fan with illumination according to claim 2, further comprising legs that support the fan casing on an inner

wall surface of the lower part of the main housing, wherein

the fan unit is movable between a placement position of the fan unit in the main housing and a maintenance position of the fan unit over the second opening by slide movement of the legs along the inner wall surface of the lower part of the main housing.

4. The ceiling mounted ventilation fan with illumination according to claim 3, further comprising guides that are engaged with the legs so as to guide the slide movement of the legs.

5. The ceiling mounted ventilation fan with illumination according to claim 1, wherein the inclination of the respective inclined surfaces of the first mounting member and the second mounting member is such that a fastening member extending through the first and second mounting members is generally oriented towards a center of the second opening.

6. The ceiling mounted ventilation fan with illumination according to claim 1 wherein a fan motor that drives the fan is provided beneath the fan, the fan motor being supported on a lower wall of the main housing.

7. The ceiling mounted ventilation fan with illumination according to claim 1, wherein a lowermost extent of the fan casing is positioned, vertically, intermediate the vertical extent of the lighting cover.

8. The ceiling mounted ventilation fan with illumination according to claim 1, wherein the first opening is provided in a wall of the main housing that extends transverse to a direction in which the lighting equipment and fan unit are spaced from each other.

9. The ceiling mounted ventilation fan with illumination according to claim 1, wherein the lamp is vertically aligned with the second opening.

10. A ceiling mounted ventilation fan with illumination comprising:

a fan unit,

an illumination unit,

a main housing in which the fan unit and the illumination unit are installed, the main housing having a first opening connected to an air outlet of the fan unit and communicating with a duct, and a second opening provided in a lower part of the main housing so as to communicate with an interior of a room, and

a cylindrical member having a shape of a circular truncated conical cylinder or polygonal truncated prismatic cylinder such that a size of lower end of the cylindrical member is greater than a size of an upper end of the cylindrical member, the cylindrical member being attached to the main housing so as to surround the illumination unit,

the fan unit comprising:

a fan, and

a fan casing positioned at a first position space, in a horizontal direction, from a second position that is above the second opening, the fan casing surrounding the fan, the fan casing having an air inlet opening directed upwardly, wherein

light from the illumination unit passes through the second opening of the main housing into the room, and air is introduced through the second opening into the main housing and the introduced air is sucked through the air

13

inlet of the fan casing into the fan unit and is discharged through the first opening into the duct by the fan unit, and

the ceiling mounted ventilation fan further comprising:

a first mounting member fixed on an upper wall of the main housing, and

a second mounting member fixed on the fan casing, wherein

the first mounting member and the second mounting member are inclined so that respective inclined surfaces of the first mounting member and the second mounting member face to the second opening, and

the fan is fixed to the upper wall of the main housing by fixing the inclined surface of the first mounting member to the inclined surface of the second mounting member.

11. The ceiling mounted ventilation fan with illumination according to claim **10**, wherein

an electrical unit for the fan unit or the illumination unit is placed on an area facing the second opening, on an inner surface of the upper wall of the main housing, and the fan unit is provided in the main housing so that a distance L1 from the inner wall surface of the upper wall of the main housing to the air inlet of the fan casing is greater than a height L2 of the electrical unit.

12. The ceiling mounted ventilation fan with illumination according to claim **11**, further comprising legs that support the fan casing on an inner wall surface of the lower part of the main housing, wherein

the fan unit is movable between a placement position of the fan unit in the main housing and a maintenance

14

position of the fan unit over the second opening by slide movement of the legs along the inner wall surface of the lower part of the main housing.

13. The ceiling mounted ventilation fan with illumination according to claim **12**, further comprising guides that are engaged with the legs so as to guide the slide movement of the legs.

14. The ceiling mounted ventilation fan with illumination according to claim **10**, wherein the inclination of the respective inclined surfaces of the first mounting member and the second mounting member is such that a fastening member extending through the first and second mounting members is generally oriented towards a center of the second opening.

15. The ceiling mounted ventilation fan with illumination according to claim **10**, wherein a fan motor that drives the fan is provided beneath the fan, the fan motor being supported on a lower wall of the main housing.

16. The ceiling mounted ventilation fan with illumination according to claim **10**, wherein a lowermost extent of the fan casing is positioned, vertically, intermediate to vertical extent of the lighting cover.

17. The ceiling mounted ventilation fan with illumination according to claim **10**, wherein the first opening is provided in a wall of the main housing that extends transverse to a direction in which the lighting equipment and the fan unit are spaced from each other.

18. The ceiling mounted ventilation fan with illumination according to claim **10**, wherein the lamp is vertically aligned with the second opening.
